"""
This code was originally written for CS 231n at Stanford University
(cs231n.stanford.edu). It has been modified in various areas for use
in the
ECE 239AS class at UCLA. This includes the descriptions of what code
to
implement as well as some slight potential changes in variable names to
be
consistent with class nomenclature. We thank Justin Johnson & Serena
Yeung for
permission to use this code. To see the original version, please visit
cs231n.stanford.edu.
"""

def affine_forward(x, w, b):
    """
    Computes the forward pass for an affine (fully-connected) layer.

    The input x has shape (N, d_1, ..., d_k) and contains a minibatch of
    N
    examples, where each example x[i] has shape (d_1, ..., d_k). We will
    reshape each input into a vector of dimension D = d_1 * ... * d_k, a
    nd
    then transform it to an output vector of dimension M.

    Inputs:
    - x: A numpy array containing input data, of shape (N, d_1, ..., d_k
    )
    - w: A numpy array of weights, of shape (D, M)
    - b: A numpy array of biases, of shape (M,)

    Returns a tuple of:
    - out: output, of shape (N, M)
    - cache: (x, w, b)
    """

    # ===== #
    # YOUR CODE HERE:
    # Calculate the output of the forward pass. Notice the dimensions
    # of w are D x M, which is the transpose of what we did in earlier
    # assignments.

def batchnorm_forward(x, gamma, beta, bn_param):
    """
    Forward pass for batch normalization.

    During training the sample mean and (uncorrected) sample variance are
    computed from minibatch statistics and used to normalize the incoming
    data.
    During training we also keep an exponentially decaying running mean
    of the mean
    and variance of each feature, and these averages are used to normalize
    data
    at test-time.

    At each timestep we update the running averages for mean and variance
    using
    an exponential decay based on the momentum parameter:

    running_mean = momentum * running_mean + (1 - momentum) * sample_mean

```

```

n
    running_var = momentum * running_var + (1 - momentum) * sample_var

    Note that the batch normalization paper suggests a different test-time
    behavior: they compute sample mean and variance for each feature using a
    large number of training images rather than using a running average.
    For this implementation we have chosen to use running averages instead since
    they do not require an additional estimation step; the torch7 implementation
    of batch normalization also uses running averages.

    Input:
    - x: Data of shape (N, D)
    - gamma: Scale parameter of shape (D,)
    - beta: Shift parameter of shape (D,)
    - bn_param: Dictionary with the following keys:
        - mode: 'train' or 'test'; required
        - eps: Constant for numeric stability
        - momentum: Constant for running mean / variance.
        - running_mean: Array of shape (D,) giving running mean of features
    - running_var: Array of shape (D,) giving running variance of features

    Returns a tuple of:
    - out: of shape (N, D)
    - cache: A tuple of values needed in the backward pass
    """
